2. The second testing framework I found in Python was Pytest. Pytest is not in the standard python library like pytest, but some developers consider this an advantage since updates to the library are not bound by updates to Python itself. Additionally, pytest does not require the creation of test classes like unittest. Pytest also requires less upfront code to begin testing because of this. Both libraries allow testing of similar types, like client and server side testing, creation of fixtures, and generators. For the simple calculator program above, the pytest library would have worked as well as the unittest library for testing.
